

1. **Research Title:** Integrated Robust and Resilient Control of Propulsion Systems for Reliability and Performance

2. **Individual Sponsor:**

Dr. Al Behbahani
AFRL/RQTE
2130 8th Street
WPAFB, OH 45433-7251
alireza.behbahani@us.af.mil

3. **Academic Area/Field and Education Level**

Aerospace Engineering, Mechanical Engineering, and Electrical Engineering: Guidance, Navigation and Control, Turbine-Engines Health Monitoring (MS or PhD level)

4. **Objectives** The role of a resilient controller is to enhance recovery of the (robust) control system from unanticipated adverse conditions and faults as well as from emergency situations by altering its operational envelope in real time. Objectives of Resilient control design are:

- Reliable and fast recovery from adverse conditions and emergency situations
- Restoration of the control configuration upon returning to normalcy or upon graceful degradation within design specifications
- Achieving trade-offs between stability and performance under disturbances and (both structured and unstructured) uncertainties within specified bounds
- Mitigation of the detrimental effects of disturbances and uncertainties

5. **Description:** Resilient control systems in critical infrastructures require increased cyber-security and state-awareness. One of the necessary conditions for achieving the desired high level of resiliency is timely reporting and understanding of the status and behavioral trends of the control system. New architectures are needed that will enhance the reliability of the system, incorporating a new Intelligent Distributed Control Networks, and development of a fuzzy-neural data fusion system for increased state-awareness of resilient control systems. The key design approach is to use the new architecture both in terms of decentralized hardware and hierarchical control system software design using smart sensors or actuators connected through high speed data bus. Traditional systems incorporate the sub-systems required to deliver the common operational picture. Reduction of those integrated sub-systems is unacceptable; therefore, introducing a decentralized architecture is going to carry with it the requirement of a seamless interaction despite being separated. Decentralization is a design process that allows a constellation capability to seek more nodes than what would be normally available when residing in the same payload. This is a measure of design success that enhances the evaluation of a system's capability and its ability to survive risk, its resilience.

6. **Research Classification/Restrictions:** Unclassified/None

7 **Eligible Research Institutions:**

DAGSI (All DAGSI Universities). PA Approval #88ABW-2017-3609.
